

This diagram depicts a Participant who has posted a Mailing List message and released a version of the Software

Lines indicate Object Properties, Squares are Classed Individuals, lowercase 'pills' are Datatype properties. Forums are almost identical to Mailing Lists, while Trackers model the TrackerItem as a Thread. SVN Commit messages are unthreaded. Note that fc:hasEvent always has an Event on the right (its rdf:range) but can have a Project, a Venue, a Thread on its left, this is convenient for querying.

Events have Documents, rather than having content directly, because an Event could produce more than one Document (eg Change Note and Release Note, or SVN log message, list of Files and Diff)

One intended extension is to define Periods, such as an inter-release Period, to which Events with appropriate datetimes belong
